

## Security of computer and server operating systems

Microsoft Forefront Client Security program offers homogeneous protection against content which is harmful for stationary computers, mobile computers and server operating systems in a company, making it easier to manage and control. Forefront Client Security program – with the use of the same effective technology of Microsoft’s protection which is used by millions of people worldwide – helps to protect against emerging dangers such as spy software, rootkits as well as traditional ones, i.e. viruses, bugs and Trojan horses. Forefront Client Security allows for reliable and effective company’s protection. Forefront Client Security program integrates with existing infrastructural software, such as Active Directory service and completes other Microsoft protection technologies ensuring better protection and closer control. There are two elements included in Microsoft Forefront Client Security solution. The first one is a protection agent – installed on stationary computers, mobile computers and server operating systems in a company – which guarantees protection in the actual time in the form of planned scanning in search of threats such as spying software, viruses and rootkits. The other element is a central management server which provides administrators with simple management and updating of the pre-configured or adjusted agents of harmful content and generating reports and alerts concerning the state of protection of their environments. More information on the topic of Forefront products is available on the Microsoft Forefront website.
